General

Firmware version

For a given firmware tag **VXY-ZK**:

- Usercode is **XYZKdbdb**
- Firmware version read via "`R 4024`" is **XYZK**

VME access through the board discrete "emergency" logic

The FPGA may be accessed via JTAG through the discrete logic as follows

- The VME address is 0xFFFC
- The bit 0 of the data sent is TMS
- The bit 1 of the data sent is TDI

For example, to read the Usercode, starting from JTAG idle (five TMS = 1 & one TMS = 0), the commands are:

```
W  FFFC  1   To Select-DR-Scan
W  FFFC  1   To Select-IR-Scan
W  FFFC  0   To Capture-IR
W  FFFC  0   To Shift-IR

W  FFFC  0   Shifting IR (Read UserCode IR = 3C8)
W  FFFC  0   Shifting IR
W  FFFC  0   Shifting IR
W  FFFC  2   Shifting IR
W  FFFC  0   Shifting IR
W  FFFC  0   Shifting IR
W  FFFC  2   Shifting IR
W  FFFC  2   Shifting IR
W  FFFC  2   Shifting IR
W  FFFC  3   Shifting IR and to Exit1-IR

W  FFFC  1   To Update-IR
W  FFFC  0   To Run_Test/Idle
W  FFFC  1   To Select-DR-Scan
W  FFFC  0   To Capture-DR

W  FFFC  0   Shifting DR
R  FFFC  0   Shifting DR (Read bit 0 of UserCode)
```

Since the Usercode register is 32 bits, the last two commands should be repeated 31 more times.

Place the **jumpers** marked in **red** in the diagram: M[2:0] = 010, and ST12 grounded to use clock from CCB.

Translation into temperatures and voltages

The output of the 7YZ0 commands is a 12-bit number that we call R_{YZ}. The measurement is:

- The FPGA temperature is $\mathrm{T_{FPGA}} = \dfrac{\mathrm{R_{00}} \times 503.975}{4096} - 273.15 \ \ [^\circ \mathrm{C}]$
- The temperature of the thermistors THERM1, THERM2 is given by

R_{XY}	377	455	55A	687	7DD	959	AF8	CB5	E87	FFF
T [° C]	15	20	25	30	35	40	45	50	55	60

- The voltage levels are $\mathrm{V_{YZ}} = \dfrac{\mathrm{R_{YZ}}}{2048} \times \mathrm{V_{YZ,Nom}}\ [\mathrm{V}]$, where $V_{YZ,\,Nom}$ is the nominal voltage level for that register. That is, $V_{10,\,Nom} = V_{13,\,Nom} = 3.3V$, $V_{11,\,Nom} = V_{17,\,Nom} = 5V$, $V_{14,\,Nom} = 2.5V$, and $V_{16,\,Nom} = 1V$.
